Learning Topical Social Sensors

Authors
Affiliations

Abstract

Social media sources such as Twitter represent a massively distributed social sensor of a rich underlying topic space ranging from social and political events to entertainment and sports news. However, given the continual evolution of social media content, querying for content from individual users or containing certain keywords or hashtags is often insufficient to retrieve the vast range of topical content available. To automate generic social sensor construction, we train a supervised learner to identify topical content over a large feature space given a small set of seed hashtags. On a corpus of approximately (choose one: 1 billion English Tweets / 40 TB of data) collected from the Twitter streaming API during 2013 and 2014 and learning for 10 diverse topics ranging from social issues to celebrity deaths to the "Iran nuclear deal", we empirically show that our learned social sensor automatically generalizes to unseen future content (including content with no hashtags) with high ranking and precision scores. Furthermore we provide an extensive analysis of features and feature types across different topics that reveals, for example, that (1) largely independent of topic, simple terms are the most informative feature followed by location features and that (2) the number of unique hashtags and tweets by a user correlates more with their informativeness than their follower or friend count. In summary, this work provides a novel, effective, and efficient way to learn topical social sensors from a seed set of hashtags requiring minimal user curation effort and offering strong generalization performance.

Introduction

Social media sites such as Twitter present a double-edged sword for users. On one hand these sources contain a vast amount of novel and topical content that challenge traditional news media sources in terms of their timeliness and diversity. Yet on the other hand they also contain a vast amount of spam and otherwise low-value content for most users' information needs where filtering out irrelevant content is extremely time-consuming. Hence, while it is widely acknowledged that social media sources can be used as topical content sensors (indeed, an entire European Union project was focused on "Social Sensor" research[1].), automatically learning high-precision sensors (i.e., ranking and retrieval methods) for arbitrary topics that generalize to future unseen content remains an open question in the literature and comprises the key problem we seek to address in this paper.

Perhaps the critical bottleneck for learning targeted topical social sensors is to achieve sufficient supervised content labeling; with data requirements often in the thousands of labels to ensure effective learning and generalization, manual labeling is simply too time-consuming for many users and crowdsourced labels are both costly and prone to misinterpretation of users' information needs. Fortuitously, hashtags have emerged in recent years as a pervasive topical proxy on social media sites — hashtags originated on IRC chat, were adopted later (and perhaps most famously) on Twitter, and now appear on other microblogs (e.g., Sina and Tencent Weibo) and even Facebook. Hence as a simple enabling insight that serves as a catalyst for effective topical social sensor learning, we leverage a (small) set of user-curated topical hashtags to efficiently provide a large number of supervised topic labels for social media content.

With the data labeling bottleneck resolved, we proceed to train supervised classification and ranking methods to learn topical content from a large feature space of source users and their locations, terms, hashtags, and mentions. On a corpus of approximately (choose one: 1 billion English Tweets / 40 TB of data) collected from the Twitter streaming API during 2013 and 2014 and covering 10 diverse topics ranging from social issues to celebrity deaths to the "Iran nuclear deal", we empirically show that two simple and efficiently trainable methods — logistic regression and naive Bayes — generalize well to unseen future topical content (including content with no hashtags) in terms of their mean average precision (MAP) and Precision@n for a range of n. Furthermore, we show that terms and locations are among the most useful features — surprisingly more so than hashtags, even though hashtags were used to label the data! And perhaps even more surprisingly, the number of unique hashtags and tweets by a user correlates more with their informativeness than their follower or friend count.

In summary, this work fills a major gap in the literature of topical social sensors and how to effectively and efficiently learn them given minimal supervision from a user. Our results suggest that these sensors generalize well to unseen future topical content and provide a novel paradigm for the extraction of high-value content from social media.

Table 1: Feature Statistics

Dataset Statistics

We crawled Twitter data using Twitter Streaming API for two years spanning 2013 and 2014 years. This type of crawling provides us with a very sparse set of data, roughly 1% of all tweets [2]. The total number of tweets collected is $829,026,458$. In the context of Twitter, we consider a list of 5 features for each tweet. Each tweet has a $From$, the person who tweeted it, and a $Time$ which is the date information of the tweet. It can also contain

- $Hashtag(s)$, keywords specified using # sign
- $Mention(s)$, another Twitter username being mentioned using @ sign
- $Term(s)$, uni-grams which we extract from the 140 characters of the tweet. These uni-grams are later cleaned to remove $Term$s with no meaning (total number of $Term$s before cleaning was $20,234,729$)

Table 1 provides more detail statistics about each feature. For each feature, we reported the count of the feature in our dataset, in addition to maximum, average, median counts of each feature across the tweets. Lower part of the table provides these counts across user dimension meaning that for example a hashtag has been used in average by 10.08 users. Last part of the table shows the statistics for the hashtag usage of our users e.g., users have used 2 hashtags in average.

Figure **??** shows details of number of tweets per month and figure **??** shows the power law plots of tweet counts and hashtag counts for users. We chose 10 topics for our experiments. Tweets are temporally divided over 2 years to provide train and test sets. Table 2 provides samples of training hashtags and number of train hashtags, test hashtags, topical tweets for each topic. Some topics such as $HumanCausedDisaster$ and $Soccor$ are more general topics and have higher number of topical tweets while some other ones such as $IranDeal$ is more specific, thus having less number of topical tweets.

Figure **??** shows distribution of tweets across different location in U.S. and international locations overall and for each topic(?).

[2]http://allthingsd.com/20101110/twitter-firehose-too-intense-take-a-sip-from-the-garden-hose-or-sample-the-spritzer—

Experimental Methodology

How we curated hashtags: need to make up good story here. Inner-annotator agreement of 3/4.

Train/validation/test split date selection – temporally .5,.1,.4

Feature selection: threshold per feature 159 and 50 (just explain rationale for lower hashtag and location thresholds).

Formal notation, how do we train/test and tune hyperparameters for a generic classifier.

Classification Algorithms

1. Naive Bayes
2. Rocchio (centroid)
3. Logistic Regression

All above over 1,000,000 features, *same* training data for all algorithms.

Not breaking down by feature type yet – that's for the feature analysis section.

Analysis

- Table of rows:alg, cols: MAP, P@k (k in 10,100,1000) with stderrs over all topics

- Could do a bar graph (below) each for MAP, P@100 with topics as major columns and algs as neighboring bars

- Anecdotal results for each topic – point out deficiency in our labels (a good thing, we generalized well from small hashtag set), manual evaluation of relevance for top-100 for best algorithm?

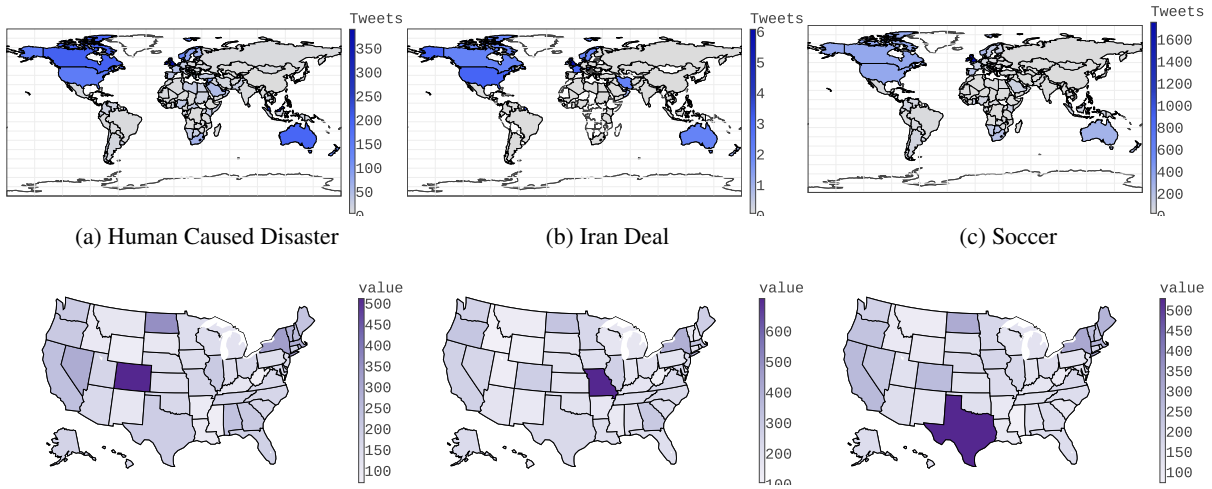
Feature Analysis

In this section, we analyze the informativeness of each feature for learning topical tweets by looking at different characteristics for each feature in our dataset. For example, one characteristic of hashtags could be the number of the tweets that contain those hashtags. Does this have an effect on importance of the hashtag when it comes to learning topical tweets or not. In this sense, this section would bring insights to the following questions:

- **What are the best features for learning social sensors, do they differ by topic? (Why?)**
- **For each feature type, do any attributes correlate with importance?**

A famous method for measuring informativeness is Mutual Information which is a measure of amount of information one random variable contains about another random variable. In order to calculate amount of information that a feature $f_k \in \{from, hashtag, mention, term, location\}$ provides w.r.t $t_i \in \{NaturalDisaster, Epidemics, ...\}$, mutual information is defined as:

$$I(t_i, f_k) = \sum_{t_i \in \{true,false\}} \sum_{f_k \in \{true,false\}} p(f_k, t_i) \log \left(\frac{p(f_k, t_i)}{p(f_k)p(t_i)} \right) \quad (1)$$



(a) Human Caused Disaster (b) Iran Deal (c) Soccer

(d) Health Epidemics (e) Social Issues (f) Space

Table 2: Test/Train Hashtag samples and statistics

Higher values for this metric indicates more informative features for the specified topic.

First, we provide mutual information values for each feature across different topics shown by boxplots in figure **??**, and average values of mutual information for each feature vs different topics shown in table 2. The last column in table 2 shows average mutual information for the feature with the standard error range provided. We make a few observations from the analysis of Table 2:

- Term features provide more information for all of the topics on average which shows the importance of uni-grams when it comes to selection of topical tweet.
- From and mention features are the least informative features for all of the topics.
- Location and Hashtag feature provide second and third most informative features respectively.
- A few topics such as irandeal and tennis are less sensitive to selection of a specific features.
- Location feature provides more information regarding HumanCausedDisaster, LBGT, and Soccer topics.
- Sorting features based on their average mean value across different topics results in the following order:

1. Term
2. Location
3. Hashtag
4. Mention
5. From

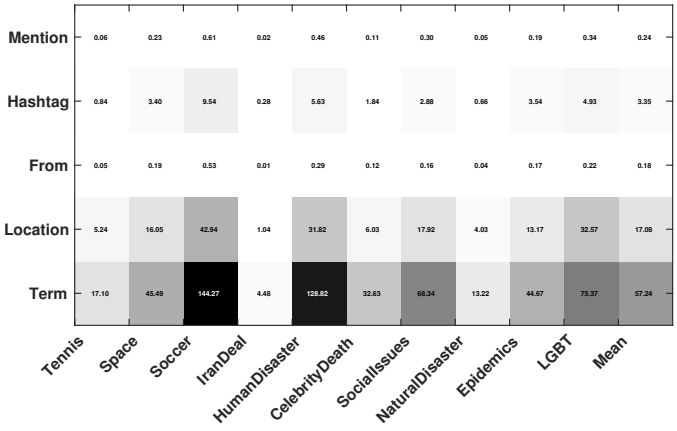

Figure 2: Average MI for different features vs. Topics, last two column show mean value and stderr across all topics

It is important to note that due to very large amount of Term features, they were cleaned based on their frequency (having at least frequency value of 100).

For each feature type, do any attributes correlate with importance? In order to give a better sense of what features are better for each topic, we provided top-5 features

Related Works

This section documents existing research on the use of social media as a sensor for topic detection on social media. Herein, we focus on related research on both events and topics detection within social media. With the consideration that events are special type of topics and can be classified as such. To see how different works address topic detection on social media, we focus on three extensively researched types of topic detection: trending topic detection, specific event detection, and tweet recommendation.

The first overarching group of works reviewed herein focus on trending topic detection methods. The majority of works detecting trending topics use bursts as the indicator of events, where a burst is defined as a sudden change in posting rates of some keywords, hashtags, etc. These can further be divided into multiple categories based on how they use bursts to extract the event. The first category, clustering-based methods, focuses on the hypothesis that trends are topical and topics are defined by the collection of relevant content; hence trends can be detected by clustered content (Petrović, Osborne, and Lavrenko 2010; Ishikawa et al. 2012; Phuvipadawat and Murata 2010; Becker, Naaman, and Gravano 2011; O'Connor, Krieger, and Ahn 2010; Weng and Lee 2011). With more focus on machine learning methods, (Wei et al. 2015) proposed a graphical model to discover latent events clustered in the spatial, temporal and lexical dimensions, while (Yamamoto and Satoh 2015) focused on the task of multi-label classification of tweets into living aspects such as eating.The second category, term-based methods focuses on the hypothesis that topics can be detected by focusing on temporal patterns of terms/keywords independent of the content of documents (Mathioudakis and Koudas 2010; Cui et al. 2012; Zhao et al. 2011; Nichols, Mahmud, and Drews 2012). Table 5: Top 5 features for each topic based on Mutual Information

third category, query-based methods, focuses on the hypothesis that trending topics can be detected by measuring user defined criteria (Albakour, Macdonald, and Ounis 2013; Sakaki et al. 2012). The fourth category, network Structure-based method, focuses on the hypothesis that trending topics can be detected by studying the network structure of users (Budak, Agrawal, and El Abbadi 2011). The final category, hybrid method of (Diplaris et al. 2012) introduced concept of Dynamic Social Containers in this work to take advantage of aggregation of mining both the structure, content, and multimedia data to index and provide personalized, context-aware search. In this work, the authors defined social sensor as analyzing the dynamic and massive amount of information provided by user with the purpose of extracting unbiased trending topics and events in addition to using social connections for recommendation.

With the purpose of comparison of methods, (Aiello et al. 2013) evaluated six trending topic detection methods on three Twitter datasets differing in time scale and topic churn rate. The authors conclude that natural language processing techniques perform well on focused topics. However, techniques mining temporal distribution of concepts are needed to handle more heterogeneous streams.

However, trending topics detection methods are not targeted. Our method differs from trending topic detection methods in that we are focusing on a set of topics that cannot necessarily be detected using bursts.Thus, trending topics detection methods are of limited relevance to the work presented hereinafter.

The second overarching group of works focuses on detection of a specific targeted topic, such as a disaster or epidemic. In a predictive study by (Kryvasheyeu et al. 2014), the authors studied the network of users and focused on choosing the best groups of users in order to achieve lead-times i.e. faster detection of disastrous event (following the concept of "friendship paradox"(Feld 1991) [3]). (Sakaki, Okazaki, and Matsuo 2013) used SVM classifier to detect earthquakes and employed a location estimation method such as Kalman Filtering for localizing it. The authors detected the occurrence of earthquakes through extracted statistical features e.g., the number and position of words in a tweet, keyword features and word context features from tweets.

Whereas the above works addressed exploiting the detection of crisis events, the following works focused on descriptive studies on disaster. The studies discuss the behavior of Twitter users during a crisis (Vieweg et al. 2010; Cheong and Cheong 2011; Starbird and Palen 2010) and do not address exploiting detection of crisis events. The studies investigated the use of social media during a crisis in order to identify information propagation properties, the social behavior of users (their retweeting behavior), information contributing to situational awareness, and the active players in communicating information. The behavioral information gleaned from these studies is exploited in this work to aid in the development of social sensors for detection of topics.

To detect health epidemics, researchers used content-based and/or structure-based methods. The content-based methods of (Culotta 2010) and (Aramaki, Maskawa, and Morita 2011) identified influenza-related tweets and correlated these tweets to United States Center for Disease Control (CDC) statistics on influenza, such as the infection and incubation rate. As for methodology, both works extracted bag-of-words as features, while the former employed single and multiple linear regression showing that multiple linear regression works better, while the latter employed SVM. Results indicated a high correlation between their estimation of influenza cases in early stages of an epidemic, and statistics from the CDC and Japan's Infection Disease

[3] On average, most people have fewer friends than their friends have

Surveillance Center. The other approach to early detection of contagious outbreaks is to use structure-based methods, (García-Herranz et al. 2012) designed a sensor based on the friendship paradox concept for early detection of contagious outbreaks. In this regard, García-Herranz et al. provided a method for choosing sensor groups from friends of random sets of users to find more central individuals in order to enforce early detection. The central assumption made in this work is that a sensor group represents more central individuals, and individuals at the center of a network are more likely to become infected than randomly-chosen members of the population. As a result, (García-Herranz et al. 2012) argued that this selection process of sensor groups helps in the early detection of outbreaks.

On the other hand, hybrid method of (Sadilek, Kautz, and Silenzio 2012), exploited tweet content and the structural information of a user's network. The authors employed a semi supervised approach to learn a SVM classifier, using n-grams as features in order to detect ill individuals. Using co-location and friendship, the authors estimated the probability of physical interaction between healthy and sick people. This enabled them to study the effect of these two factors of social activity (co-location for contact network and friendship for social ties) on public health.

The limitations of these studies centers on the fact that the proposed methods are only valid for detecting a single topic. These methods used a primitive methods for curating the data e.g., querying keyword earthquake. In addition, there is no discussion within these works on how these methods can be generalized for other topics.

Another set of studies have moved towards creating more generalizable methods. Using a dataset of 55,000 news articles and 121,000 tweets, (Krestel et al. 2015) compared four different methods of language model, topic model, logistic regression, and boosting, to evaluate recommended tweets for a given news article.. (Yan, Lapata, and Li 2012; Chen et al. 2012) also focused on tweet recommendation. Their methods considered the users twitter profile, including tweet and retweet history, and social relations as features. Coupled with tweet popularity, the methods are able to generate tweet recommendations. With the purpose of photo recommendation on social media websites, (Chiarandini et al. 2013) analyzed the user logs of pageviews, navigation patterns between photostreams. The authors used collaborative filtering method and built a stream transition graph to analyze common stream topic transitions to this end.

On retweet prediction, (Can, Oktay, and Manmatha 2013; Xu and Yang 2012; Petrovic, Osborne, and Lavrenko 2011) used classification-based approaches using tweet-based and author-based features. However, (Can, Oktay, and Manmatha 2013) took advantage of visual cues from images linked in the tweets, and (Xu and Yang 2012) employed social-based features in addition to tweet author-based features. Different from the other two works, (Xu and Yang 2012) performed the analysis from the perspective of individual users. (Petrovic, Osborne, and Lavrenko 2011) worked on retweet prediction of real-time tweeting with online learning algorithms and claimed that performance is dominated by social features, but that tweet features add a substantial boost. These studies showed that temporal features have a stronger effect on messages with low and medium volume of retweets compared to highly popular messages, and user activity features can further improve the performance marginally.
